Utility Patent Application Transmittal

(Only for new non-provisional applications Under 37 CFR 1.53(b))

ASSISTANT COMMISSIONER FOR PATENTS
Washington, D. C. 20231Case Docket No. 0325.00353Date: June 28, 2000

Sir:

Transmitted herewith for filing is a patent application of:

Inventor(s): Andrew Wright

For: CIRCUIT FOR IMPLEMENTING PRODUCT TERM INPUTS

Enclosed are:

1. ☒ Specification (17 pages); Claims (5 pages); Abstract (1 page)
2. ☒ 7 sheets of formal drawings.
3. ☒ Oath or Declaration Total Pages 2
 - a. ☒ Newly executed (original or copy)
 - b. ☐ Copy from a prior application (37 CFR 1.63(d))
(for continuation/divisional with Item 5 completed)
 - c. ☐ Copy of Revocation of Previous Power
4. ☐ Incorporation By Reference (usable if Item 3b is checked)
The entire disclosure of the prior application, from which a copy of the oath or declaration is supplied under Item 3b, is considered as being part of the disclosure of the accompanying application and is hereby incorporated by reference therein.
5. ☐ If a Continuing Application, check appropriate box and supply the requisite information below and in a preliminary amendment:

☐ Continuation ☐ Divisional ☐ Continuation-in-part (CIP)
of prior application no.:
6. ☒ An assignment to CYPRESS SEMICONDUCTOR CORP. along with PTO form 1595.
7. ☐ A PTO Form 1449 with a copy of the references not previously cited.
8. ☒ Return Receipt Postcard
9. ☐ Other:

The filing fee has been calculated as shown below:

	No. Filed	No. Extra	Fee	Amount
Basic Fee	--	--	--	\$690.00

CIRCUIT FOR IMPLEMENTING PRODUCT TERM INPUTS

Field of the Invention

The present invention relates to a method and/or
5 architecture for input circuits generally and, more particularly,
to a method and/or architecture for implementing a circuit for
product term inputs.

Background of the Invention

A programmable logic device (PLD) provides an economical
and efficient means for implementing predetermined Boolean logic
functions in an integrated circuit. Such a device consists of,
generally, an AND plane configured to generate predetermined
product terms in response to a plurality of inputs, a group of
15 fixed/programmable OR gates configured to generate a plurality of
sum-of-product (SOP) terms in response to the product terms, and a
number of logic elements (i.e., macrocells) configured to generate
a desired output in response to the sum-of-products terms. The
sum-of-products terms can also be generated using programmable NOR-
20 NOR logic.

The arrangement and operation of components within the PLD are programmed by architecture configuration bits. The architecture configuration bits are set prior to normal operation of the PLD. The configuration bits can be stored in volatile memory (i.e., SRAM) or non-volatile memory (i.e., EEPROM/flash).
5 The bits are set using an operation called "programming" or "configuration".

Depending upon the Boolean function implemented, the plurality of inputs to the AND plane of the PLD can require a number of input signals, digital complements of the input signals, and logic levels (i.e., "0" or "1"). The plurality of inputs are presented by product term input circuits. In order to maximize the number of input signals to a PLD (i.e., avoid sacrificing an input to generate a logic level), the product term input circuits need to
10 be able to select either an input signal, a complement of the input signal, or a logic level.

Referring to FIG. 1, a schematic diagram of a circuit
15 illustrating a conventional polarity switch is shown. The circuit 20 has an inverter 22, a PMOS transistor 24, a NMOS transistor 26, a PMOS transistor 28, a NMOS transistor 30, and an inverter 32. The transistors 24 and 26 form a first transmission gate and the

0325.00353
CD00029

transistors 26 and 28 form a second transmission gate. An enable signal EN is presented to an input of an inverter 34 via a pad 36. An output of the inverter 34 presents a signal to an input of the inverter 22, a gate of the transistor 24, and a gate of the transistor 30. An output of the inverter 22 presents a signal to a gate of the transistor 26 and a gate of the transistor 28. An input signal IN is presented to an input of the inverter 32 and a first source/drain of the transistors 28 and 30. An output of the inverter 32 is presented to a first source/drain of the transistors 24 and 26. A second source/drain of the transistors 24, 26, 28, and 30 are connected to form a node at which an output signal OUT is presented. Depending upon the state of the enable signal EN, either the signal IN or a complement of the signal IN will be presented as the signal OUT.

Referring to FIG. 2, a schematic diagram of a circuit 36 illustrating a memory cell generating the enable signal EN of FIG. 2 is shown. The circuit 36 comprises a non-volatile memory cell 38 and a driver circuit 40. An output of the memory cell is presented to an input of the driver circuit 40. The driver circuit 40 comprises an inverter 42, a transistor 44, a transistor 46 and a transistor 48. The signal from the memory cell 38 is presented to

0325.00353
CD00029

an input of the inverter 42, a gate of the transistor 46 and a gate and source of the transistor 48. An output of the inverter 42 presents the signal EN to the circuit 20 and a gate of the transistor 44. A source of the transistor 44 is connected to a source of the transistor 46 and a supply voltage VCC. A drain of the transistors 44, 46, and 48 are connected together.

The circuit 20 can present only the signal IN or a complement of the signal IN. The circuit 20 requires eight transistors. In order to select between the signal IN, a complement of the signal IN, and a logic level, a product term input circuit would require two of the circuits 20. The product term input circuits account for a significant portion of the transistors in a PLD. Doubling the number of transistors needed for a product term input circuit with redundant logic is undesirable. Since the product term input circuits account for a significant portion of the transistors in a PLD, a product term input circuit that could select between signal polarities and logic levels with fewer transistors would be desirable.

Summary of the Invention

The present invention concerns an apparatus comprising a polarity switch. The polarity switch may comprise a number of transmission gates. An output of the polarity switch may
5 selectably present either (i) a signal that varies in response to a control signal or (ii) a predetermined logic level that is independent of the control signal.

The objects, features and advantages of the present invention include providing a method and/or architecture for implementing a product term input circuit that may (i) be implemented in a complex programmable logic device (CPLD), (ii) provide a reduction in the number of transistors needed for implementing product term inputs, (iii) provide a reduction in area for implementing the same number of product term inputs, (iv)
15 provide the capability to implement a larger number of product term inputs in a given area and/or (v) provide a reduction in interconnect length and/or a reduction in delay on a CPLD.

Brief Description of the Drawings

These and other objects, features and advantages of the present invention will be apparent from the following detailed description and the appended claims and drawings in which:

5 FIG. 1 is a block diagram illustrating a conventional polarity switch;

FIG. 2 is a block diagram illustrating control of the polarity switch of FIG. 3 by a non-volatile memory cell;

10 FIG. 3 is a block diagram conceptually illustrating a polarity switch with a 0 or 1 over-ride;

FIG. 4 is a schematic diagram illustrating a transistor implementation of the polarity switch of FIG. 3;

FIG. 5 is a schematic diagram illustrating a transistor implementation of a memory cell of FIGS. 3 and 4;

15 FIG. 6 is a block diagram illustrating a preferred embodiment of the present invention;

FIG. 7 is a schematic diagram illustrating a polarity switch implemented in accordance with a preferred embodiment of the present invention;

20 FIG. 8 is a block diagram illustrating the polarity switch of FIG. 7 implemented in the context of a memory based PLD;

FIG. 9 is a schematic diagram illustrating an embodiment of the present invention; and

FIG. 10 is a schematic of an alternate embodiment of the present invention.

5

Detailed Description of the Preferred Embodiments

Referring to FIG. 3, a block diagram of a circuit 100 illustrating a product term input circuit is shown. The circuit 100 may comprise two memory cells 102 and 104 and two speed-optimized tri-state inverters 106 and 108. The memory cells 102 and 104 may be programmed, in one example, using a single wordline (e.g., WL) and a number of bitlines (e.g., BL[1:0] and BLB[1:0]). However, other configurations of wordlines and bitlines may be implemented. For example, common bitlines and independent wordlines may be implemented without affecting operation of the circuit 100. The memory cell 102 may have an output that may present a signal (e.g., CB1) to an inverting input and a non-inverting input of the inverter 106. The memory cell 104 may have an output that may present a signal (e.g., CB0) to an inverting input and a non-inverting input of the inverter 108. An input signal (e.g., IT) may be presented to an inverting input of the

0325.00353
CD00029

inverter 106 and a non-inverting input of the inverter 108. A digital complement of the input signal IT (e.g., ITB) may be presented to a non-inverting input of the inverter 106 and an inverting input of the inverter 108. An output of the inverters 106 and 108 may be connected together to form an output node. An output signal (e.g., PT_IN) may be presented at the output node. Example operations of the circuit 100 may be summarized as in the following TABLE 1:

TABLE 1

C0	CB0	C1	CB1	IT	ITB	PT_IN
1	0	1	0	0	D	1
1	0	1	0	D	0	1
1	0	1	0	1	1	z
1	0	0	1	X	/X	/ITB=IT
0	1	1	0	/X	X	/IT=ITB
0	1	0	1	1	D	0
0	1	0	1	D	1	0

where D indicates that the signal does not affect the signal PT_IN, X indicates multiple states, and / indicates a logical inversion.

Referring to FIG. 4, a more detailed block diagram of the circuit 100 illustrating an implementation of the inverters of FIG. 3 is shown. The circuit 100 may comprise memory cells 102 and 104.

0325.00353
CD00029

The memory cells 102 and 104 may be connected to the same bitlines (e.g., BL and BLB) and have independent wordlines (e.g., WL0 and WL1, respectively). Each of the circuits 106 and 108 may be implemented, in one example, with four transistors. The inverter 106 may comprise a transistor 110, a transistor 112, a transistor 114, and a transistor 116. The inverter 108 may comprise a transistor 118, a transistor 120, a transistor 122, and a transistor 124.

Referring to FIG. 5, a schematic diagram of a memory cell of FIGS. 3 and 4 is shown. The memory cell may comprise a transistor 126, a transistor 128, a transistor 130, a transistor 132, a transistor 134 and a transistor 136. The signal WL may be presented to a gate of the transistor 126 and a gate of the transistor 128. The signal BL is presented to a source of the transistor 126. The signal BLB is presented to a source of the transistor 128. A drain of the transistor 126 may be connected to a drain of the transistor 130, a drain of the transistor 132, a gate of the transistor 134 and a gate of the transistor 136. A drain of the transistor 128 may be connected to a drain of the transistor 134, a drain of the transistor 136, a gate of the transistor 130, and a gate of the transistor 132. A source of the

0325.00353
CD00029

transistors 130 and 134 may be connected to a supply voltage (e.g., VPWR). A source of the transistors 132 and 136 may be connected to a ground potential (e.g., VGND). When transistors having a substrate terminal are used to implement the memory cell, the substrate terminals of the transistors 126, 128, 132 and 136 may be connected to the ground potential VGND. The substrate terminals of the transistors 130 and 134 may be connected to the supply voltage VPWR. However, other substrate connections may be implemented to meet design criteria of a particular application. The memory cell may present a configuration bit signal (e.g., Cx) at the node formed by the drains of the transistor 126, 130 and 132. A digital complement of the configuration bit signal (e.g., CBx) may be presented at a node formed by the drains of the transistors 128, 134 and 136.

Referring to FIG. 6, a block diagram of a circuit 200 illustrating a preferred embodiment of the present invention is shown. The circuit 200 may be implemented as a product term input circuit of a programmable logic device. The circuit 200 may have an input that may receive the signal IT, an input that may receive the signal ITB, an input that may receive the signal C0, an input that may receive the signal C1, and an output that may present the

0325.00353
CD00029

signal PT_IN. The signals C0 and C1 may be configuration bits of a programmable logic device. The circuit 200 may be configured to present the signal C0 or the signal C1 as the signal PT_IN in response to the signals IT and ITB. By selecting appropriate values for the signals C0 and C1, the circuit 200 may be configured to present the signal PT_IN as (i) a logic level that is independent of the signals IT and ITB or (ii) a signal that may change state similarly to either the signal IT or the signal ITB. An example operation of the circuit 200 may be summarized as in the following TABLE 2:

TABLE 2

C0	C1	PT_IN
0	0	0
0	1	ITB
1	0	IT
1	1	1

The circuit 200 may be implemented to balance a sacrifice of stage speed for a reduction in die size, interconnect length and overall delays.

The circuit 200 may comprise a transmission gate 202 and a transmission gate 204. The transmission gates 202 and 204 may be implemented, in one example, as CMOS transmission gates. The

0325.00353
CD00029

signal C1 may be presented to an input of the transmission gate 202. The signal ITB may be presented to an active HIGH control input of the transmission gate 202. The signal IT may be presented to an active LOW control input of the transmission gate 202. The
5 signal C0 may be presented to an input of the transmission gate 204. The signal ITB may be presented to an active LOW control input of the transmission gate 204. The signal IT may be presented to an active HIGH control input of the transmission gate 204. The signals IT and ITB may be used as control signals for the transmission gates 202 and 204.

When the signal IT is in a first state (e.g., a digital 0, or LOW), the transmission gate 202 will generally present the signal C1 as the signal PT_IN. When the signal IT is in a second state (e.g., a digital 1, or HIGH), the transmission gate 204 will
15 generally present the signal C0 as the signal PT_IN. The signals C0 and C1 may control the circuit 200 such that the signal PT_IN may be (i) in the same state as the signal IT, (ii) in the same state as the signal ITB, (iii) a logical 0, or (iv) a logical 1.

Referring to FIG. 7, a more detailed schematic diagram
20 illustrating an implementation of the circuit 200 is shown. The circuit 200 may comprise a transistor 206, a transistor 208, a

0325.00353
CD00029

transistor 210, and a transistor 212. The transistors 206 and 212 may be implemented as one or more PMOS transistors. The transistors 208 and 210 may be implemented as one or more NMOS transistors. However, other types and polarities of transistors may be implemented accordingly to meet the design criteria of a particular application. The signal IT may be presented to a gate of the transistor 206 and a gate of the transistor 208. The signal ITB may be presented to a gate of the transistor 210 and a gate of the transistor 212. The signal C0 may be presented to a source of the transistor 208 and a source of the transistor 212. The signal C1 may be presented to a source of the transistor 206 and a source of the transistor 210. A drain of the transistors 206, 208, 210 and 212 may be connected together to form a node 214. The signal PT_IN may be presented at the node 214. The circuit 200 may be implemented, in one example, using transistors having a substrate terminal. When the circuit 200 is implemented with transistors having a substrate terminal, the substrate terminal of the transistors 206 and 212 may be connected to the supply voltage VPWR. The substrate terminals of the transistors 208 and 210 may be connected to the supply voltage ground VGND. However, other

0325.00353
CD00029

connections to the substrates may be implemented to meet the design criteria of a particular application.

Referring to FIG. 8, a block diagram illustrating the circuit 200 implemented in the context of a memory based programmable logic device 220 is shown. The PLD 220 may have configuration bits stored in a number of memory cells. In one example, the PLD 220 may have a memory cell 222 and a memory cell 224. The memory cell 222 may be configured to store a first value in response to the wordline WL0 and the bitlines BL and BLB. The memory cell 222 may have an output that may present the signal C0. The signal C0 may be indicative of a value of a configuration bit (e.g., a logical 0 or 1) stored in the memory cell 222. Similarly, the memory cell 224 may be configured to store a second value in response to the wordline WL1 and the bitlines BL and BLB. The memory cell 224 may have an output that may present the signal C1. The signal C1 may be indicative of a value of a configuration bit stored in the memory cell 224. The memory cells 222 and 224 may be configured to source and sink a current.

Referring to FIG. 9, a schematic diagram illustrating an implementation of the circuit 220 of FIG. 6 is shown. The memory

0325.00353
CD00029

cells 222 and 224 may be implemented in accordance with the transistor circuit described in connection with FIG. 5.

Referring to FIG. 10, a schematic diagram of a circuit 300 illustrating an alternative embodiment of the present invention is shown. The circuit 300 may comprise a circuit 302, a circuit 304, a circuit 306, and a circuit 308. The circuit 302 may be implemented similarly to the circuit 200 described in connection with FIGS. 7 and 8. The circuits 304, 306, and 308 may comprise, in one example, a CMOS transistor pair configured as an inverter circuit. A signal (e.g., CB0) may be presented to a gate of a transistor 310 and a transistor 312. A source of the transistor 310 may be connected to the supply voltage VPWR. A source of the transistor 312 may be connected to the ground supply VGND. A drain of the transistors 310 and 312 may be connected together to form an output node 314. The signal C0 may be presented at the output node 314 in response to the signal CB0.

A signal (e.g., CB1) may be presented to a gate of a transistor 316 and a transistor 318. A source of the transistor 316 may be connected to the supply voltage VPWR. A source of the transistor 318 may be connected to the ground supply VGND. A drain of the transistors 316 and 318 may be connected together to form an

0325.00353
CD00029

output node 320. The signal C1 may be presented at the output node 320 in response to the signal CB1.

The signal IT may be presented to a gate of a transistor 322 and a transistor 324. A source of the transistor 322 may be connected to the supply voltage VPWR. A source of the transistor 324 may be connected to the ground supply VGND. A drain of the transistors 322 and 324 may be connected together to form an output node 326. The signal ITB may be presented at the output node 326 in response to the signal IT.

The circuits 302-308 may be implemented with PMOS and NMOS transistors having substrate terminals. The substrate terminals of the PMOS transistors may be connected to the supply voltage VPWR. The substrate terminals of the NMOS transistors may be connected to the supply voltage ground VGND.

The present invention may provide a transmission gate based polarity switch having a programmable 0 or 1 over-ride. A product term input circuit implemented in accordance with the present invention may provide the functions of previous product term input circuits with fewer transistors.

While the invention has been particularly shown and described with reference to the preferred embodiments thereof, it

0325.00353
CD00029

will be understood by those skilled in the art that various changes in form and details may be made without departing from the spirit and scope of the invention.

CLAIMS

1. An apparatus comprising:

a polarity switch comprising a number of transmission gates, wherein an output of said polarity switch selectably presents either (i) a signal that varies in response to a control
5 signal or (ii) a predetermined logic level that is independent of said control signal.

2. The apparatus according to claim 1, wherein said number of transmission gates is two.

3. The apparatus according to claim 1, wherein said output signal is selected in response to a first configuration signal and a second configuration signal.

4. The apparatus according to claim 1, further comprising a first storage element connected to an input of a first transmission gate and a second storage element connected to an input of a second transmission gate.

0325.00353
CD00029

5. The apparatus according to claim 1, wherein said control signal is an input term.

6. An apparatus comprising:

a first circuit configured to present a first stored value to an input node in response to a first state of a control signal; and

a second circuit configured to present a second stored value to said input node in response to a second state of said control signal.

7. The apparatus according to claim 6, wherein said first and second circuits comprise transmission gates.

8. The apparatus according to claim 7, wherein said transmission gates comprise a CMOS transistor pair.

9. The apparatus according to claim 6, wherein said first and second circuits comprise a first and second storage element, respectively.

0325.00353
CD00029

10. The apparatus according to claim 9, wherein said first and second storage elements contain the same or different data.

11. The apparatus according to claim 10, wherein said data comprises configuration bits.

12. The apparatus according to claim 9, wherein said first and second storage elements are configured to source or sink a current.

13. The apparatus according to claim 6, wherein said apparatus comprises a product term input circuit of a programmable logic device.

14. An AND plane of a programmable logic device comprising one or more apparatus according to claim 6.

15. The apparatus according to claim 6, wherein said control signal comprises an input term.

0325.00353
CD00029

16. The apparatus according to claim 15, wherein said apparatus is programmed to present (i) said input term, (ii) a digital complement of said input term, or (iii) a logic level to said input node.

17. The apparatus according to claim 16, wherein said logic level is a digital 0 or 1.

18. A method for providing a product term input of a programmable logic device comprising the steps of:

(A) presenting a first stored value to an input node in response to a first state of a control signal; and

(B) presenting a second stored value to said input node in response to a second state of said control signal.

19. The method according to claim 18, wherein said control signal comprises an input term.

20. The method according to claim 18, further comprising the steps of:

0325.00353
CD00029

(C) generating a first logic level at said input node in response to said first and said second stored values being programmed with a first value;

(D) generating a second logic level at said input node in response to said first and said second stored values being programmed with a second value;

(E) generating a signal at said input node that has a state similar to said control signal in response to said first stored value being programmed with said first value and said second stored value being programmed with said second value; and

(F) generating a signal at said input node that has a state similar to a digital complement of said control signal in response to said first stored value being programmed with said second value and said second stored value being programmed with said first value.

0325.00353
CD00029

ABSTRACT OF THE DISCLOSURE

An apparatus comprising a polarity switch. The polarity switch may comprise a number of transmission gates. An output of the polarity switch may selectably present either (i) a signal that varies in response to a control signal or (ii) a predetermined logic level that is independent of the control signal.
